

# **Performance of the FOCUS 2010 Software Packages for Performing Tier 1 Ground Water Assessments in the EU**

R L Jones, J J T I Boesten, M Klein, and E van den Berg

5 January 2011

## **Introduction**

The Ground Water Work Group of FOCUS prepared a revised version of the Tier 1 procedures used to assess potential for movement to ground water. These changes have been extensively described in the report of the work group (FOCUS, 2009). Since the issuing of the report, several minor changes have been made in the software packages. This report documents the changes that have been made and the impact of these changes on the predicted concentrations.

## **Changes in the Software Packages**

The changes in the software packages were minor. For PELMO and PRZM the only change in the models was the change in the concentration below which the  $K_{oc}$  was represented by a linear isotherm. In PEARL this concentration is  $10^{-24}$  µg/L so “sub-molecular level” whereas this concentration was originally 0.01 µg/L in PELMO and PRZM. In a number of cases when the values of the Freundlich exponent ( $1/n$ ), were significantly below 0.9, this difference led to differences in calculated leaching concentrations predicted by PEARL and PELMO. Therefore, this minimum concentration for a Freundlich isotherm was dropped to  $10^{-20}$  µg/L in PELMO and PRZM (while different from PEARL, this difference is insignificant). To the best of our knowledge no evidence is available showing a dependency of the Freundlich exponent to this concentration level, also not when adsorption isotherms were measured for concentrations in the liquid phase differing several orders of magnitude (eg., Boesten and van der Pas, 1988).

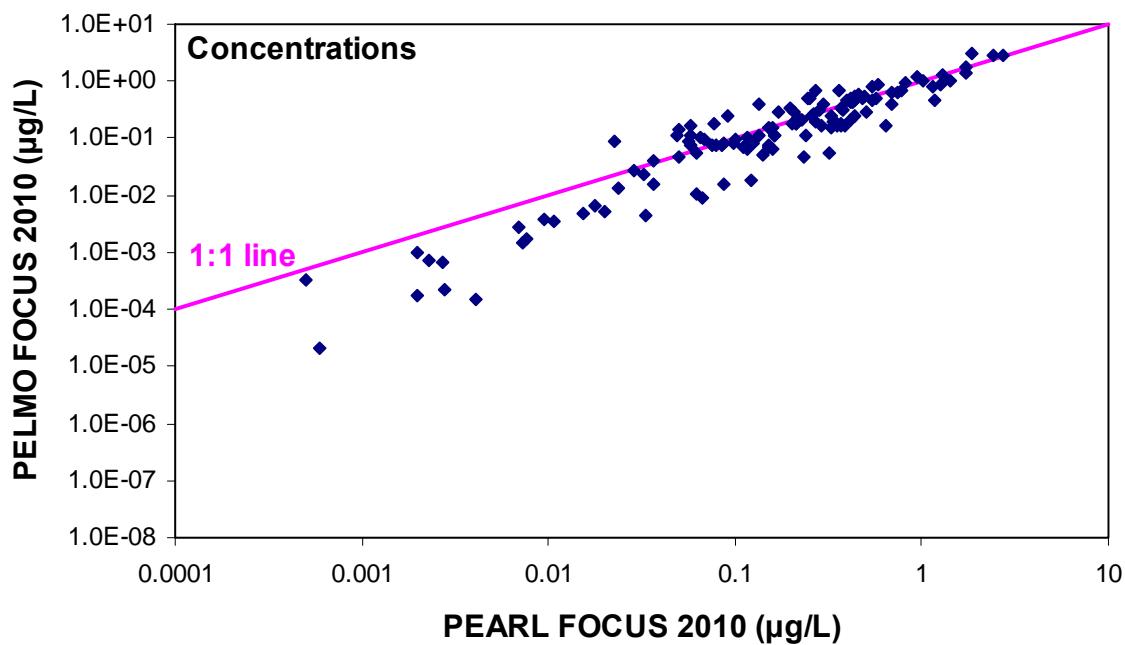

In PEARL, the water balances changed slightly (on the order of a few mm) because a revised version of SWAP is now used in PEARL. In addition the spring points for winter cereals and winter oil seed rape have been added (as prescribed in FOCUS, 2009) and the application date for the second crop in the Sevilla cabbage scenario has been corrected. The addition of the spring points and the correction of the application date decreased the PECgw for these scenarios.

In PELMO and PRZM, the default value for the Q10 value has been set at 2.58 and in PEARL the Arrhenius activation energy  $E_A$  has been set to 65.4 kJ/mol. The simulations in FOCUS (2009) were performed with a Q10 of 2.2 and an  $E_A$  of 54 kJ/mol. This change in Q10 and  $E_A$  resulted in increases in the 80<sup>th</sup> percentile concentration of up to a factor of three, with the largest increases occurring for northern location/crop combinations (Table A1-1). Some southern location/crop combinations showed relatively minor decreases in the PECgw values as a result of the increases in Q10 and  $E_A$ .

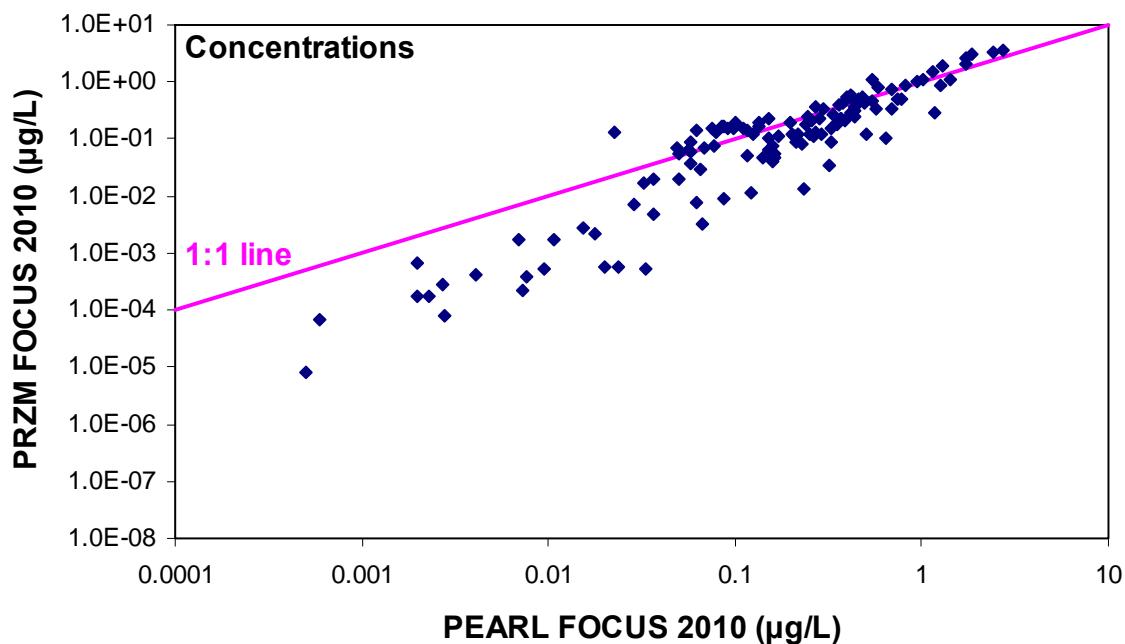

### **Comparison of Results with Previous Results**

Simulations were conducted with the three software packages for pesticide D with all 125 location/crop combinations assuming a Q10 of 2.58 and an  $E_A$  of 65.4 kJ/mol. A single application at 1 kg ai/ha was assumed to occur the day before plant emergence. For those location/crop combinations with two cropping periods, single applications of 1 kg ai/ha were made during each of the cropping periods. For apples, citrus, grass, and vines, the applications were assumed to occur on May 1. The results of these simulations are presented in Tables A1-1 to A1-7 along with the results presented in FOCUS (2009) for the FOCUS 2000 versions of the software packages.

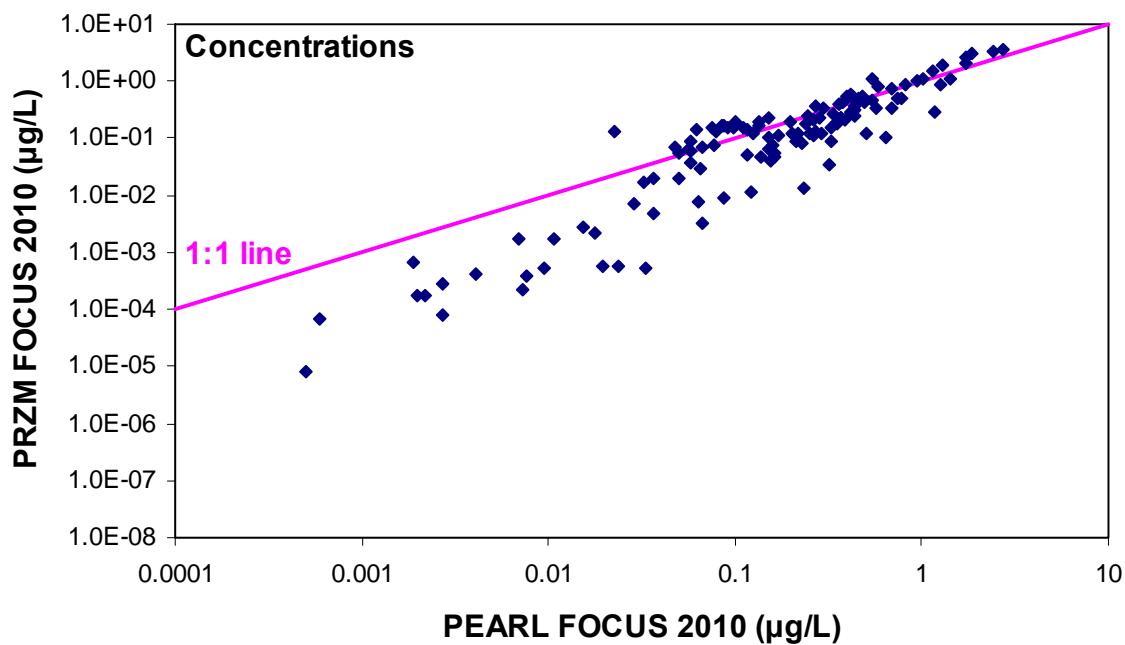

The comparisons between the predictions of the three models (Figures 1-3) remained roughly the same as shown in FOCUS (2009). One exception to this statement is that the changes in the concentration below which the  $K_{oc}$  was represented by a linear isotherm and in the Q10 and  $E_A$  increased the difference between PEARL and both PELMO and PRZM for some of the crop/location combinations where the values of PECgw were below 0.01 µg/L (this occurred only in Thiva and Sevilla). However, in this specific example this difference in these low PECgw values does not change the outcome of the regulatory assessment. Table 1 shows the effect of these changes on predicted PECgw values of pesticide D for potatoes and tomatoes in Sevilla and Thiva. For these four cases, the effect of the change in the concentration below which the  $K_{oc}$  was represented by a linear isotherm reduced the concentrations in PELMO and PRZM more than the effect of increasing Q10 (which could either increase slightly or decrease slightly the predicted PECgw value), while the effect of the  $E_A$  increase in PEARL increased the predicted PECgw. However, investigating the increase in these differences between PEARL and both PELMO and PRZM for these low values of PECgw is beyond the scope of this release procedure.

**Figure 1.** Comparison of PECgw predicted by PEARL and PELMO for all 125 FOCUS 2010 scenarios.

**Figure 2.** Comparison of PECgw predicted by PRZM and PELMO for all 125 FOCUS 2010 scenarios.

**Figure 3. Comparison of PECgw predicted by PRZM and PEARL for all 125 FOCUS 2010 scenarios.**

**Table 1. Effect of Q10/EA and the lower cutoff on the Freundlich isotherm on the predicted PECgw**
